App Proposal

Submitted by: Lord Raizen I. Espinosa

1. App Proposal

Coffee App

The problem, in one sentence

My coffee is inconsistent because I struggle to keep track of my recipes and the variables that can affect it like grind size, roast type, and brewing time.

Who is this for

This is for me and people like myself (coffee enthusiasts). I brew with three methods, moka pot, french press, and cold brew, using three different hand grinders and a coffee scale, and right now I keep this all in my head or scattered across notes instead of anywhere consistent. I forget what ratio worked last time and have to re-guess grind settings every time I switch roast or brew method.

Core features (MVP)

#	Feature	What the user does	What happens
1	Ratio Calculator	User inputs coffee and water	The calculator says the ratio and its strength
2	Grind Setting	User inputs their roast type, brew type, and grinder	A grind setting is given
3	Timer/Stopwatch	User can use the stopwatch to track the brewing time	A stopwatch tracks time allotted
4	Notes	User can write down things about the recipe like its taste or extraction rate	The brew data is saved

Stretch goals

1. Have notes gather the inputs of the user and fill it in a recipe template
2. Have more than just grams as a unit of measure
3. Include other brewing styles like phin
4. Support light roasts

Data the app needs to remember

- Thing 1: (recipe) - fields it needs: brew method, coffee, water, ratio, strength label, roast level, grind setting, and brew time
- Thing 2: (grinder profile) - fields it needs: brew type and roast level

Content I need to gather (not just data structure)

The grinder profile above is just the shape of the data, the actual values still need to be researched and entered by hand before the app is useful:

- Click/grind settings for the Comandante C40 (Red Clix), Timemore C3ESP, and Kingrinder K2
- One setting per combination of brew method (moka pot, french press, cold brew) and roast level (medium, dark)
- This is 3 grinders x 3 brew methods x 2 roast levels = 18 individual values to look up or test before the grind suggester is fully populated

Screens you'll need

1. Home - Is the main page where the user can start a brew or quickly access the tools of the app.
2. Calculator - Calculates the coffee to water ratio
3. Roast + Grind - Asks for the level of roast (medium up to dark)
4. Timer - This is a stopwatch so the user can track the time it took to make the coffee. Coffee can taste differently based on how long it took for it to be made. Espresso fans for instance like their espressos to be double the volume of coffee grounds used within 30 seconds as that is the most optimal.
5. Notes - A place where the user can write down whatever they have in mind regarding the brew they made. Will eventually have the feature where it will save the variables such as coffee and water quantity in order to be in a recipe template the user can easily save.

One risk

I wonder if this app is way too ambitious and I am biting off more than I can chew. I will need to gather the correct data needed for this app to give the correct information. That means having to make sure I look up the grind settings across all three brew types, three grinders, and both roast levels, and confirm they're accurate, before the grind suggester actually works as intended.
